ful plant, whose odoriferous flowers render delicious the fresh of the goats who feel much them. At the upper end of the plain, grasses and lichen faintly struggle against the volcanic matter. At 1500 totes above the sea, they reached a stable commonly called _the English_ Halfly, consisting of a cavern included between two rocks. Here they spent the night, gathering considerably from cold. Next morning; after tea hours walk, they came to a small plain _called Alto Yana_, where person called _Nesora_ were collecting snow for the use of the inhabitants of the coasts. Then began the _Malaysy_ a tract entirely desitute of rounds, covered with fragments of lava, which, sinking beneath the feet, rendered the second yar laborious. The guides now earnestly described them then proceeds farther and were found, on examination, never to have themselves reached the summit. At the certivity of the Malaysy, however, the travellers come in a small plant, whence they saw using the cone of the _plana_. This hillock it is extremely steep, and is an covered with volcanic sals and fragments of pumice same, as to render the ascent securely possible. They ascended only by following a current of old lava, the wrecks of which formed a wall of scorious rocks, by grasping pointed which, in their hour until the reached the top. This volcano appeared to Humbols the most difficult to ascend of any he had seen, except that of vanilla or Mexico.

On arriving at the summit, our traveler was surprised to find scarcely room to sit down. The crater was enclosed with a small circular wall of pore phylrite lava, with basis of pichstones. This wall, at all little distance, has the appearance of a small cylinder or a truncated cone. It would have entirely blocked up the approach to the crater, had there not been a branch on the east side, then which which they descended into the funnel. They found it of an elliptic form, 300 feet in length, and 200 in breadth, is remarkable, that this dimension are onely a fifth part of those of the crater of Vestrain. In fact, very laid volcanoes usually throw out the matter by lateral openings, so that some of the greatest among the Aidee how we're small patterns at the summit. The inside of the funnel indicated the appearance of a crater which had not thrown out fire for thousands of years. There were none of those layers of ecories and shells, which mark recent volcanic action, the floor was streetwed with pigments of story lines, which the action of time had detected from his sites. The strata along the edges were very irregularly plided over each other, exhibiting various groteesque ramifications. The lineings will se now while its surface, owing to the action of sulphuric acid gas on pitchcomporphyr. The aspect of the valley is rather curious than awiln. "The majority of the site consists in its deviation above the (here) of the ocean, in the profound solitude of those lofty, gions, and the immense space over which the eye ranged.

The view from this point is described by Humboldt as interesting in a very peculiar manner. He observes, " Traveller have learnt by experience, that views from the summit of very lofty mountains

are neither so beautiful, picturesque, or varied, as those from the summit of heights which do not be used that of Vestrain, Rigi, or Fuy-de-Dome, Co-lessal mountains, such a Chimbongo, Antiama, or Mount Rosa, compose in large e mass, that the plains, covered with rich vegetation, are seen only in the immunity of distance, where a blue and ve young tree is uniformly spread over the landscape. The Peak of Tenerife, from its slender form and local position, turning the advantage of less lofty summits to those which arise from very great heights. We not only discover from in top a vast expansion of sea, but we can also the freeze of Tenerife, and the inhabited part of the coasts, in a proximity fitted to produce the near beautiful contrasts of form and colouring. The volcano seems as if it settled, with its mass, the little isle which serves for its basis, and shows by from the buson of the waters to a bright three times before the region where the clouds float in the summer." The remarkable transparency of the atmosphere increases greatly the apparent proximity in which the hanlets, staryards, and gardens on the coast are behold.

The Peak appears to Humboldt to be composed entirely of volcanic products, without any mixture of primitive rocks. It is specially distinguished by the vast quantity of obiskies is substantial not found in the immediate vicinity of almost any other volcano. To alternates with, and passes into punters, in a manner which coverdust our traveller that pumice was merely turned obsidian. These two rocks, together with a poppy consisting of Western lava in a basis of pitchstone, composed the whole upper part of the Peak. Although the crater was entirely silent, yet, near the summit, vapaton, which condened into pure water, issued from different spiracles, called the Neentific of the Peak.

The active volcano of Tenerife are considered by Humboldt to be merely literal eruptions of the great volcano. The only one recently trip operation is the volcano of Caherra, situated on the west side of the Peak. After a long silence, I began its discharge on the night of the ski of Alton 1758. A hollow and cilled sound was first heard, like that of distant lumber, then a loufer roise, like that of matter in violent chultancy sites which another sound, which resembled a great discharge artillery. A short interval it inspected, till the required subsequent began to ascend. Four months were opened, of which the two highest threw up only red-hat stones. The third period out later, has slowly and it is fortunately surrounded by a rumparts of rocks, the internal between which and the volcano must be filled up, before the stream could reach the cultivated fields.

Humboldt observed the other islands merely by Aspect of sailing along their coasts. Lacercet exhibited every the other marks of linking here recently perched by volc Islands, some agency. This appears to have taken place in 1700, when nine villages were carefully destroyed. The summit of all great volcano did not appear to exceed 300 toises. The coast of Gradoans is distinguished by rocks of basalt 000 or 600 feet high, which frown in perpendicular walls over the ocean,
